

# Long-Baseline Neutrino Experiment Analysis Techniques

## PhysStat- $\nu$

Christopher Backhouse

California Institute of Technology

September 19, 2016

# Overview

- ▶ LBL oscillation physics
- ▶ T2K analysis techniques
- ▶ NOvA analysis techniques
- ▶ Can we form 1D frequentist intervals for  $\delta_{CP}$  with good coverage?

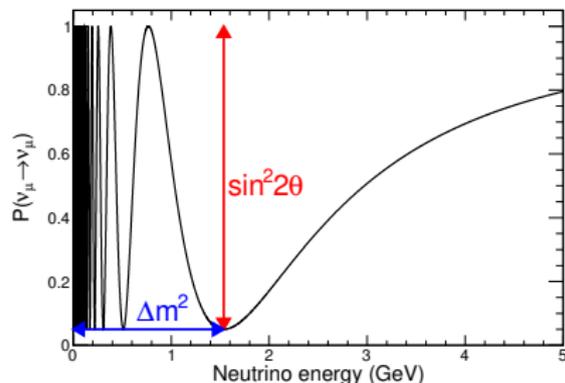

Apologies to KamLAND, MINOS, OPERA, DUNE, HyperK. . .

All opinions are my own, and do not reflect the views of either collaboration

# LBL oscillation physics

## $\nu_\mu$ survival probability

- ▶ Two flavor approx. works well here
- ▶  $P_{\mu\mu} \approx 1 - \sin^2 2\theta_{23} \sin^2 \left( \frac{\Delta m_{32}^2 L}{4E} \right)$
- ▶  $\theta_{23} \approx 45^\circ \rightarrow$  almost all  $\nu_\mu$  expected to disappear at oscillation max.

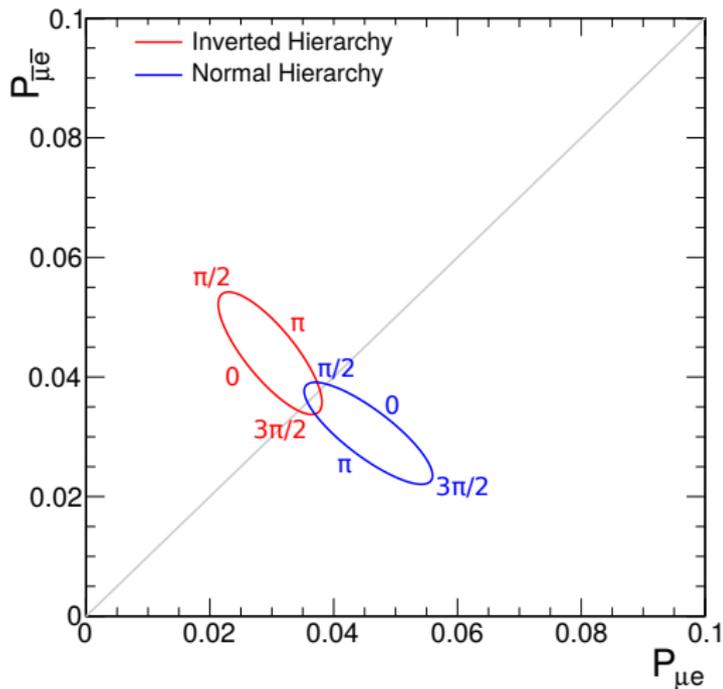

## $\nu_\mu \rightarrow \nu_e$ transition probability

- ▶  $P_{\mu e} \approx \sin^2 2\theta_{13} \sin^2 \theta_{23} \sin^2 \left( \frac{\Delta m_{32}^2 L}{4E} \right) + f(\text{sign}(\Delta m_{32}^2)) + f(\delta_{CP})$
- ▶  $\theta_{13}$  only  $8.5^\circ$  degrees, most  $\nu_\mu$  go to  $\nu_\tau$  instead
- ▶ Look for deviations due to hierarchy (matter effects) and CP-violation

## $\times 2$ for antineutrinos

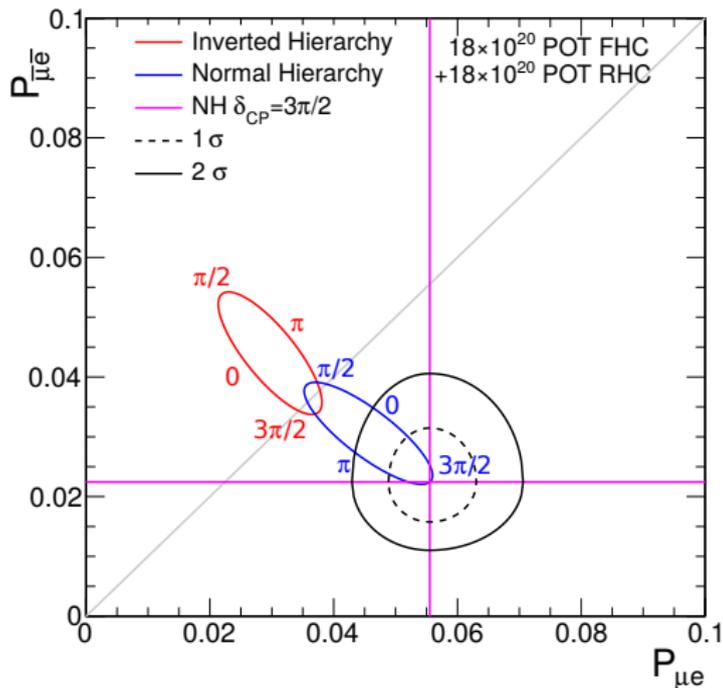

## Principle of the $\nu_e$ measurement

- ▶ To first order, NOvA measures  $P(\nu_\mu \rightarrow \nu_e)$  and  $P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e)$  evaluated at 2GeV
- ▶ These depend differently on  $\text{sign}(\Delta m_{32}^2)$  and  $\delta_{CP}$

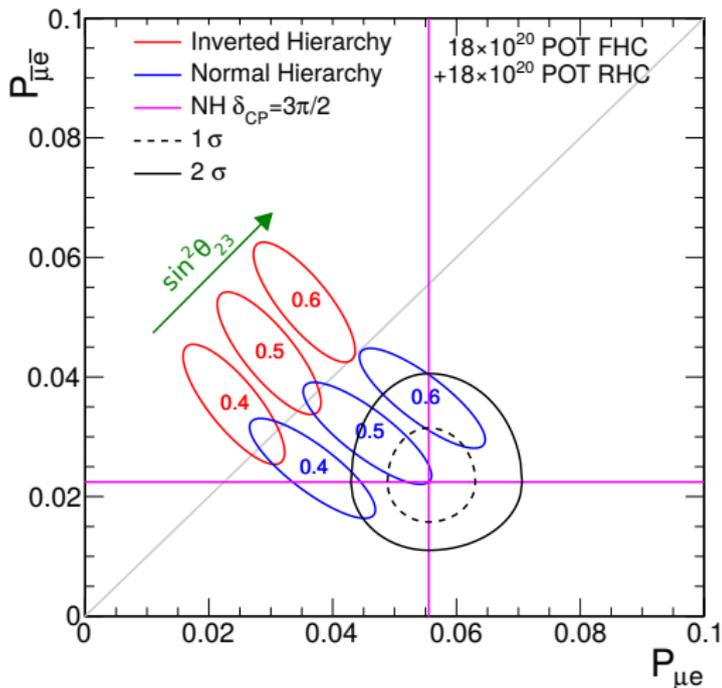

# Principle of the $\nu_e$ measurement

- ▶ To first order, NOvA measures  $P(\nu_\mu \rightarrow \nu_e)$  and  $P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e)$  evaluated at 2GeV
- ▶ These depend differently on  $\text{sign}(\Delta m_{32}^2)$  and  $\delta_{CP}$
- ▶ Ultimately constrain to some region of this space

## Principle of the $\nu_e$ measurement

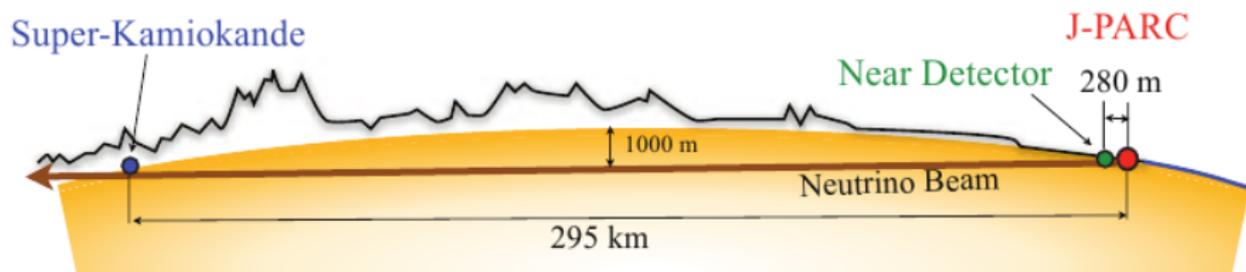

- ▶ To first order, NOvA measures  $P(\nu_\mu \rightarrow \nu_e)$  and  $P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e)$  evaluated at 2GeV
- ▶ These depend differently on  $\text{sign}(\Delta m_{32}^2)$  and  $\delta_{CP}$
- ▶ Ultimately constrain to some region of this space
- ▶  $P$  also  $\propto \sin^2 \theta_{23}$ 
  - < 0.5: “lower octant”
  - > 0.5: “upper octant”

T2K

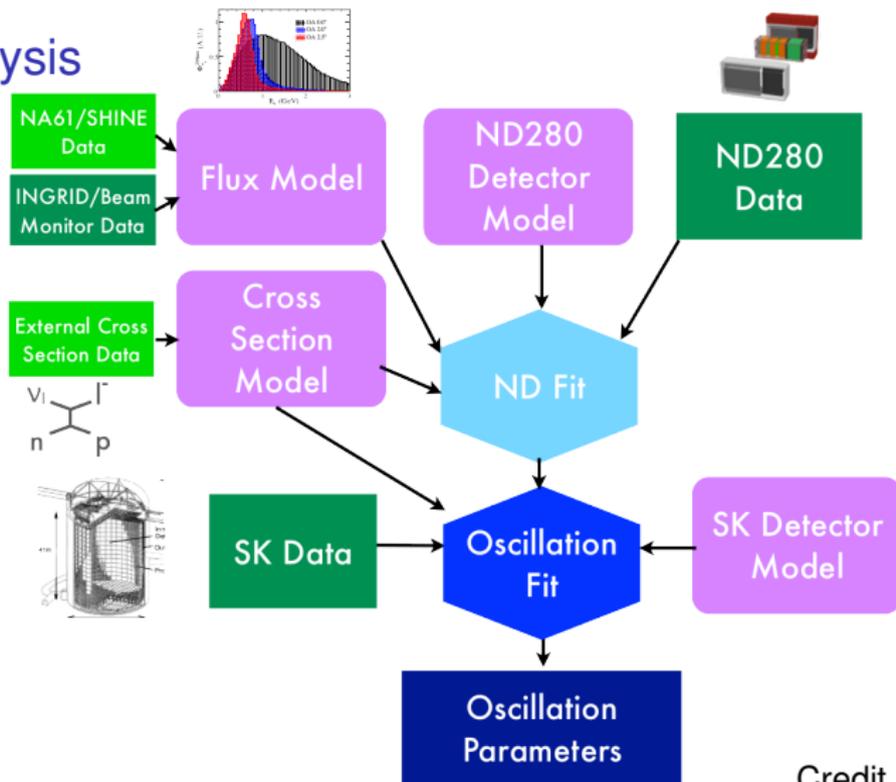

The logo for the T2K experiment features the letters 'T2K' in a bold, dark red, sans-serif font. A thick green line is drawn over the letters, starting from the bottom left, passing under the 'T' and '2', peaking over the 'K', and ending at the bottom right. A shorter, wavy blue line is positioned below the green line on the left side, under the 'T'.

## T2K overview

- ▶  $\nu_\mu \rightarrow \nu_e$   $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  and  $\nu_\mu \rightarrow \nu_\mu$   $\bar{\nu}_\mu \rightarrow \bar{\nu}_\mu$
- ▶ Cross-section and flux constraints from Near Detector (ND280) and external experiments (NA61/SHINE)

# T2K analysis

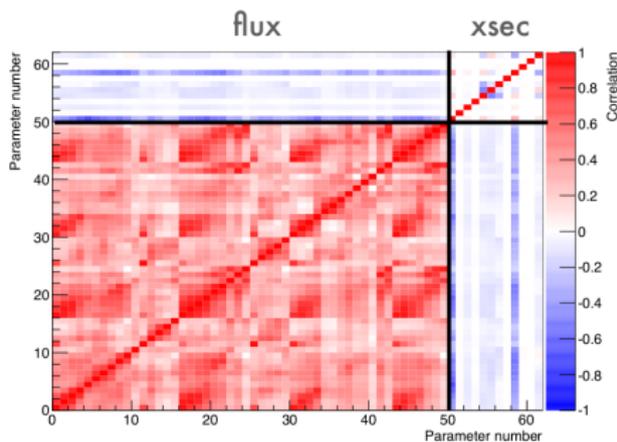

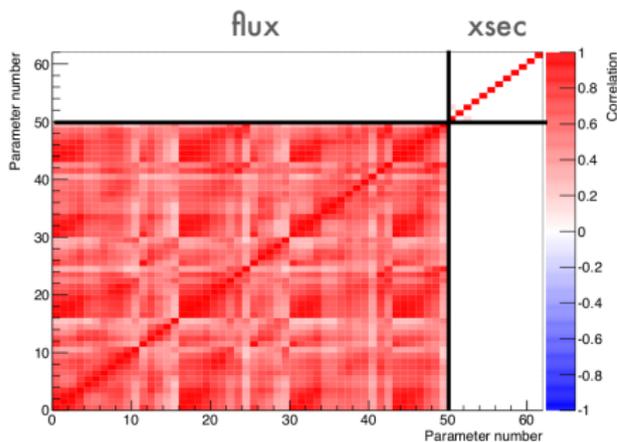

Credit Asher Kaboth

- ▶ Constrain parameters in xsec/flux model using ND280 and external data
- ▶ Appropriate if model knobs fully cover possibilities in reality

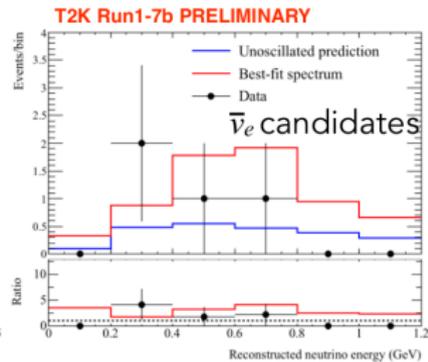

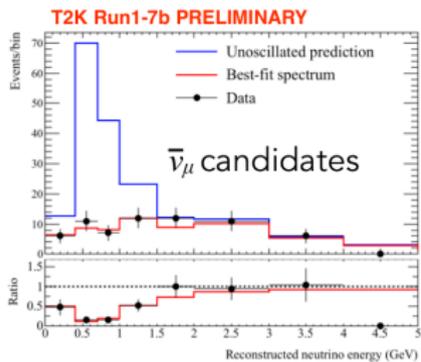

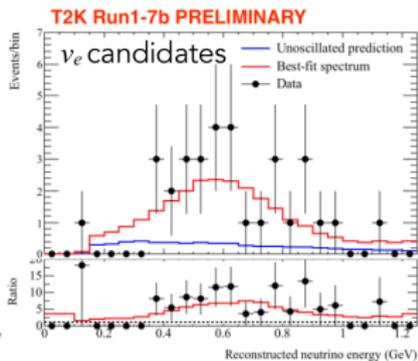

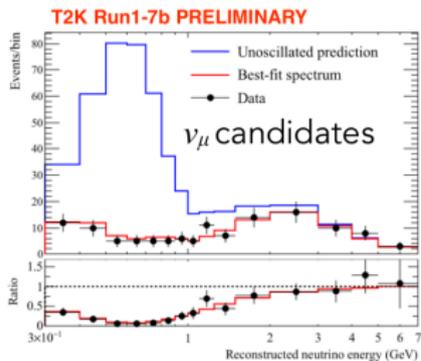

## Error matrix

- ▶ Correlation matrix constrained by fit to ND data
- ▶ See upcoming VALOR talks

- ▶ Use of a correlation matrix appropriate if parameter measurements are gaussian

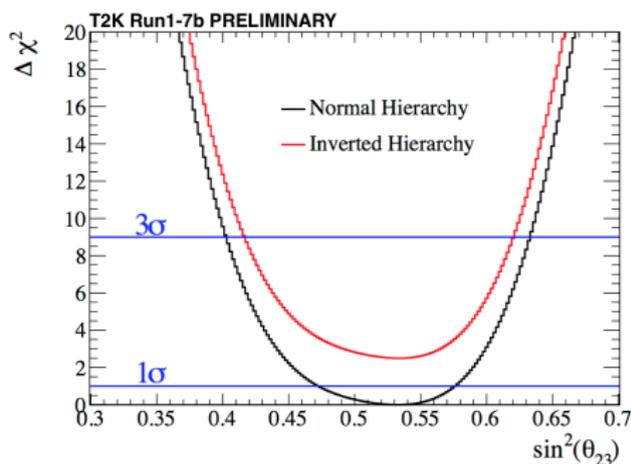

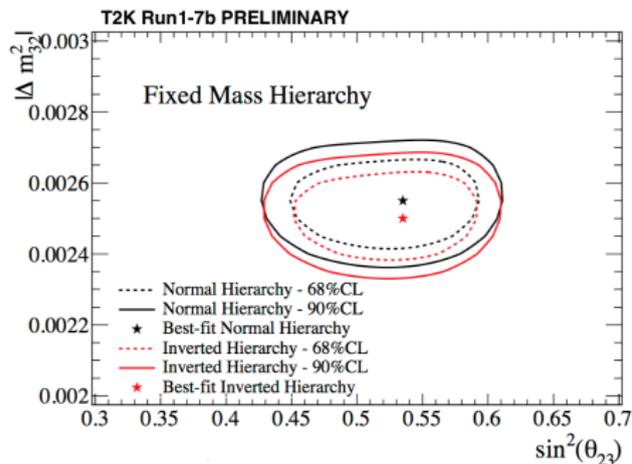

# T2K FD data

Multiple analysis approaches

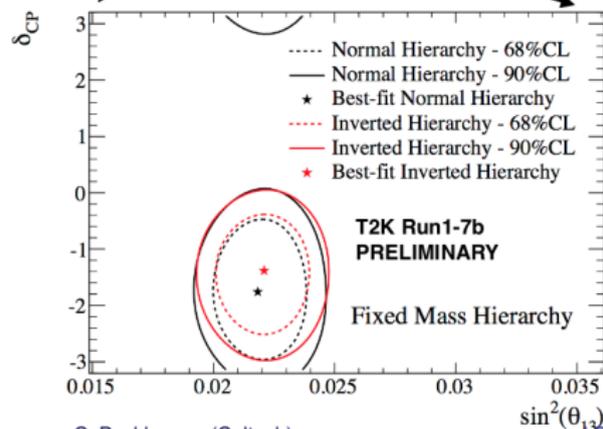

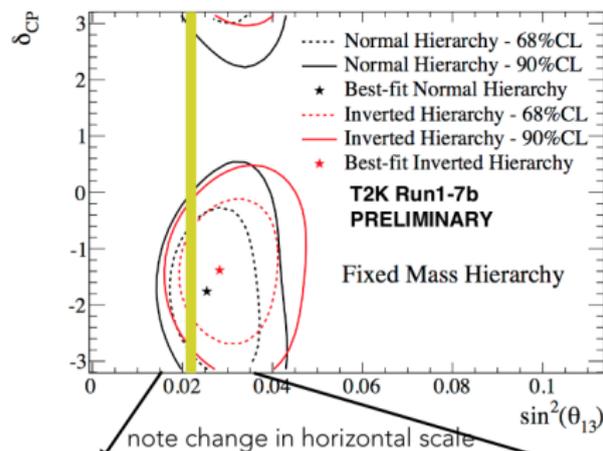

- ▶ Frequentist  $\Delta\chi^2$  fit
  - ▶ Profile over systematics
- ▶ Bayesian Ihood fit
- ▶ Bayesian MCMC, simultaneous with ND

# T2K results

- ▶ This parameter pairing dominated by  $\nu_\mu$  survival
- ▶ Bread-and-butter contour in frequentist stats, gaussian limit

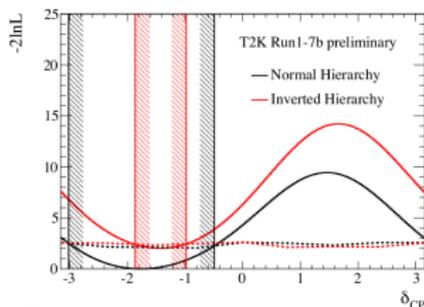

## T2K results

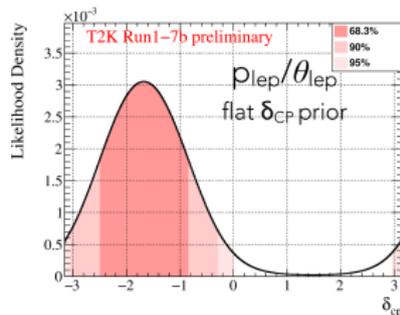

- ▶ Fixed gaussian  $\Delta\chi_{crit}^2$  (“up value”)
- ▶ Analyze each hierarchy independently
- ▶ Some gain from including external reactor  $\theta_{13}$  constraint

# T2K $\delta_{CP}$ ranges

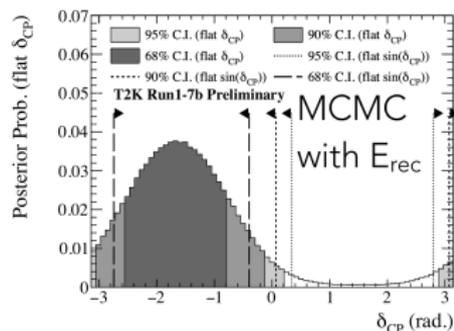

FC 90% C.L. crit. values

Bayes, prior flat in  $\delta$

Bayes, priors compared

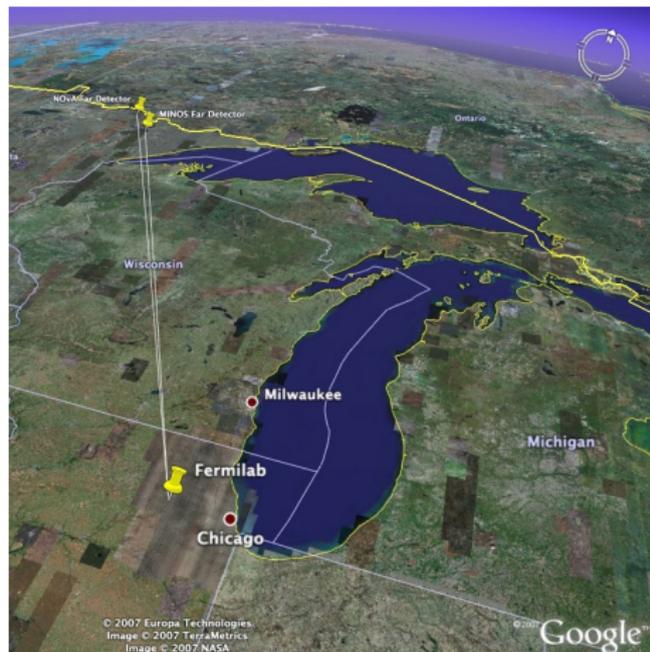

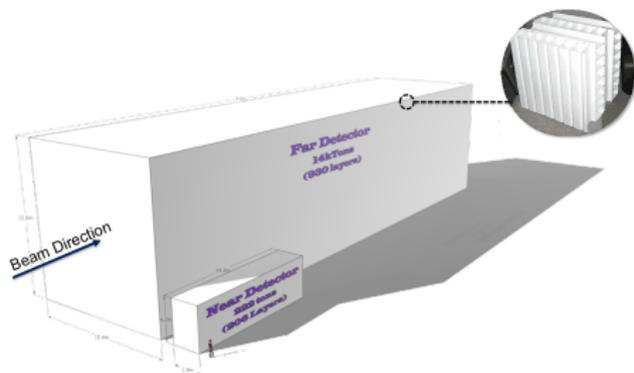

- ▶ Results from different approaches similar, not identical
- ▶ Maximal  $\theta_{23}$  and minimal sensitivity to hierarchy help consistency?

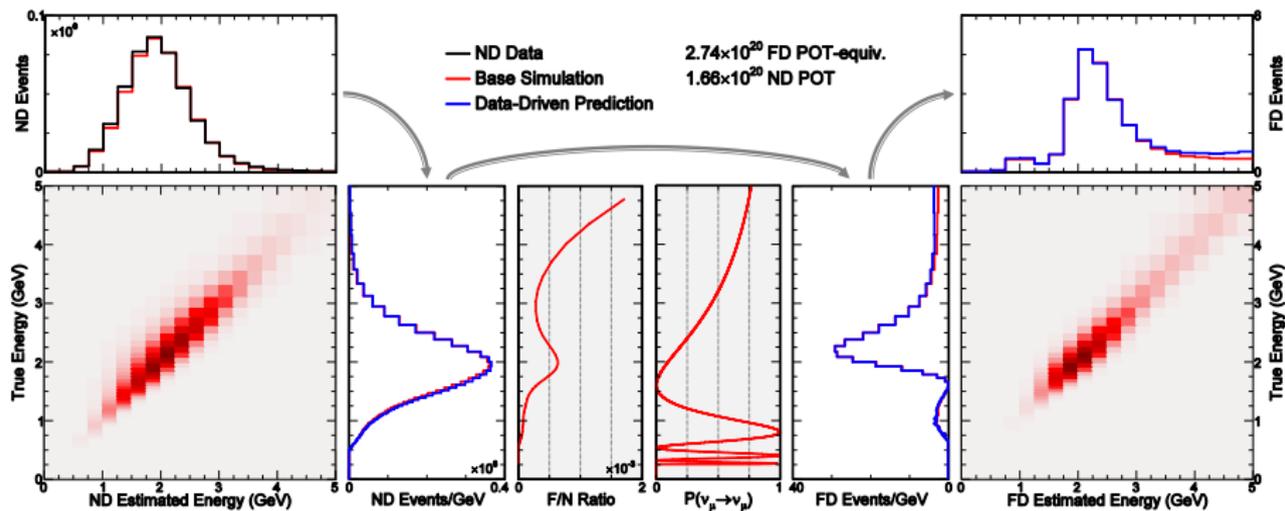

# NOvA overview

- ▶  $\nu_\mu \rightarrow \nu_\mu$  and  $\nu_\mu \rightarrow \nu_e$  channels
- ▶  $\bar{\nu}_\mu \rightarrow \bar{\nu}_\mu$  and  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  soon
  
- ▶ ND and FD are functionally identical

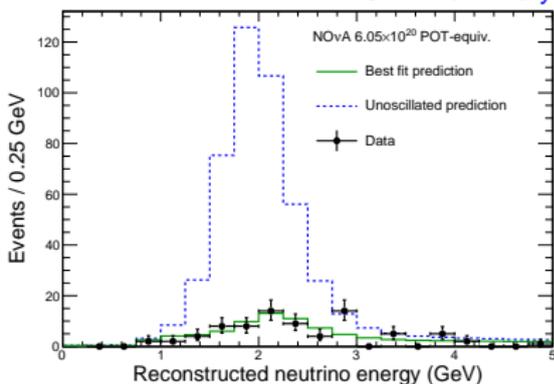

# NOvA FD prediction

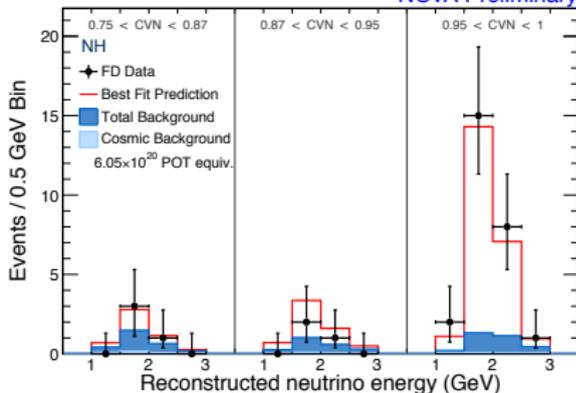

- ▶ “Extrapolate” ND data to FD prediction (via plenty of Monte Carlo)
- ▶ Assess systematics by varying MC and pushing through the whole chain
- ▶ Still some hand tweaking of parameters based on ND observations
- ▶ Should be more robust against unknown unknowns

# NOvA data

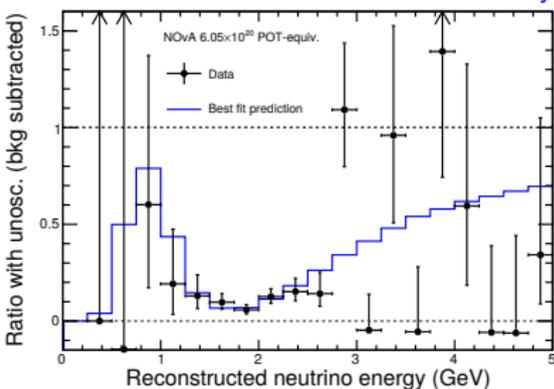

NOvA Preliminary

NOvA Preliminary

NOvA Preliminary

## ► Log-likelihood fit

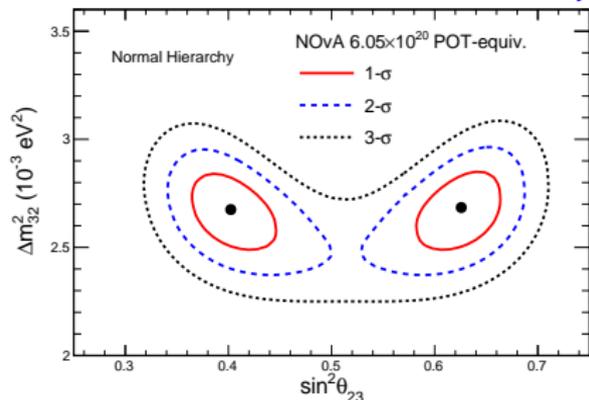

$$\mathcal{L}(N|\lambda) = \frac{\lambda^N e^{-\lambda}}{N!}$$

$$\Delta\chi^2 = -2 \ln \frac{\mathcal{L}(N|\lambda)}{\mathcal{L}(N|N)}$$

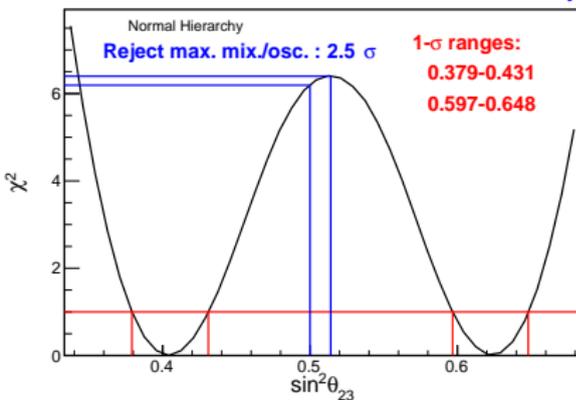

$$= 2 \left( \lambda - N + N \ln \frac{N}{\lambda} \right)$$

# NOvA $\nu_\mu$ results

NOvA Preliminary

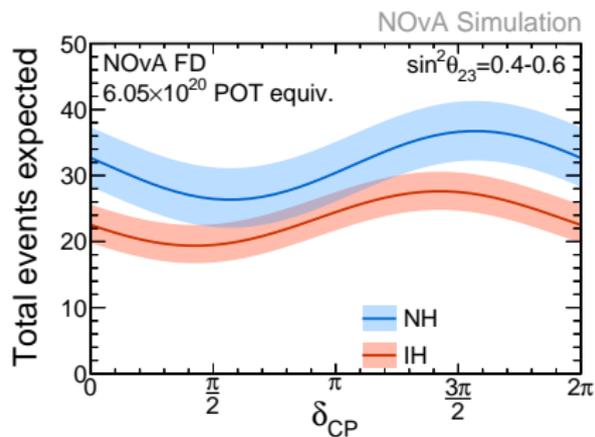

NOvA Preliminary

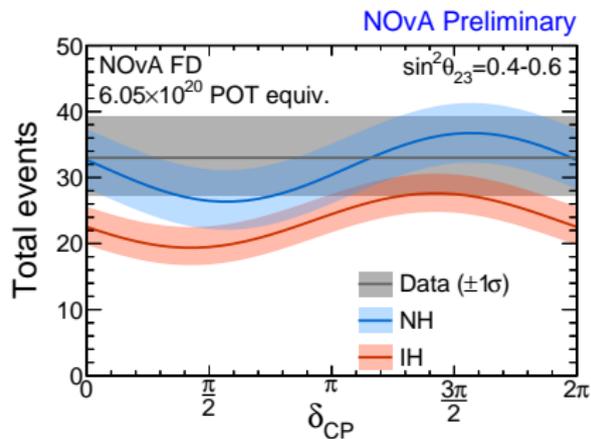

- ▶ Constant  $\Delta\chi_{\text{crit}}^2$  shown here
- ▶ Systematic parameters profiled over
- ▶ FC corrections have minimal impact
  
- ▶ Prefer non-maximal mixing, at what sig. exactly do we reject maximal?
- ▶ Evaluate FC experiments at  $\sin^2 \theta_{23} = 0.5$ , best fit  $\Delta m^2$  given this  $\theta_{23}$
- ▶ Slightly increase rejection power

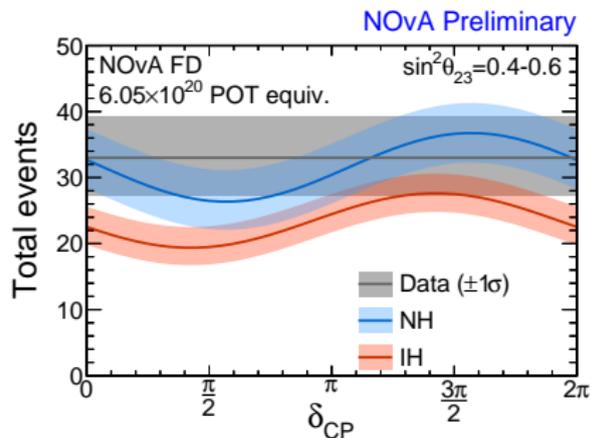

# NOvA $\nu_e$ results

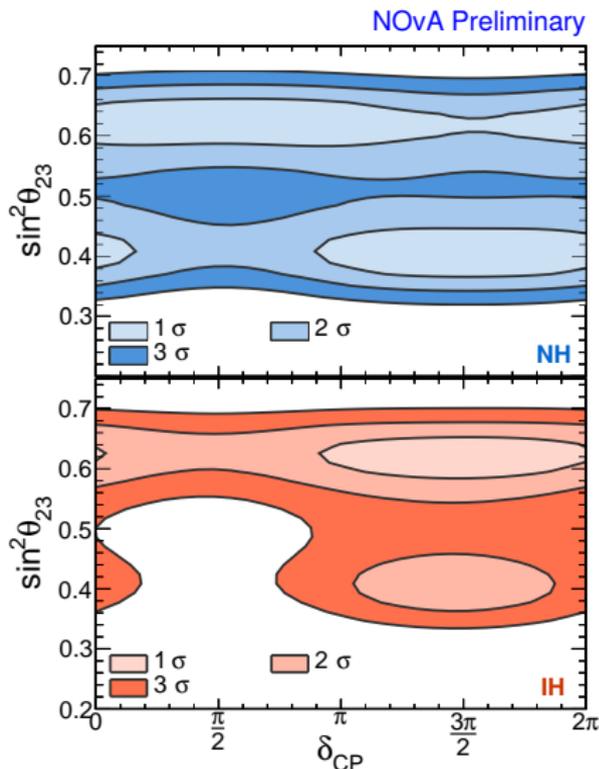

# NOvA $\nu_e$ results

# NOvA $\nu_e$ results

- ▶ Lots of interesting parameter correlations
- ▶ Extracted  $\delta_{CP}$  conclusions depend on what you do with the other parameters

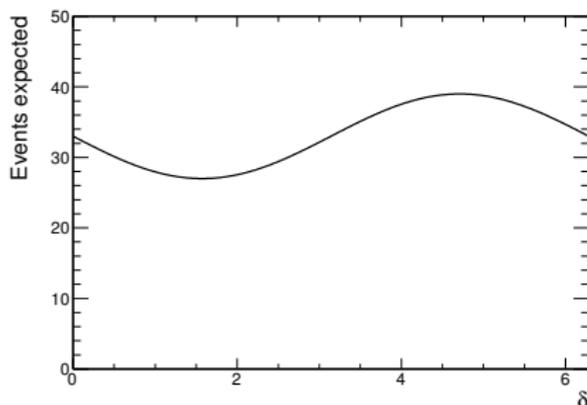

# An interesting case study

## Coverage

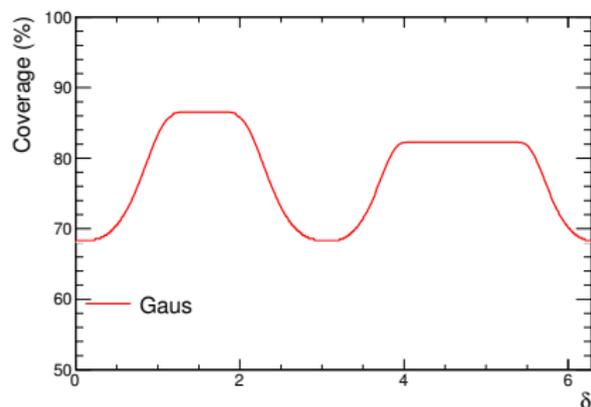

- ▶ Frequentist coverage means: “if the true value of parameter  $x$  is  $A$ , 68% of experiments will include  $A$  in their confidence interval for  $x$ ”
- ▶ FC procedure achieves this almost tautologously by throwing mock experiments at each  $A$  and finding the  $\Delta\chi_{\text{crit}}^2$  that would have included that  $A$  in 68% of the experiments
- ▶ In the presence of a parameter  $y$  not displayed on the plot (a “nuisance parameter”)
- ▶ Want correct coverage *no matter the true value of that parameter*
- ▶ Obviously impossible in general, infinite array of possible values for  $y$ , all requiring different critical values in principle
- ▶ But *e.g.* for two gaussian variables profiling over  $y$  gives correct coverage, even without invoking FC corrections
- ▶ So how does it work out in practice for our experiment?

## The toy

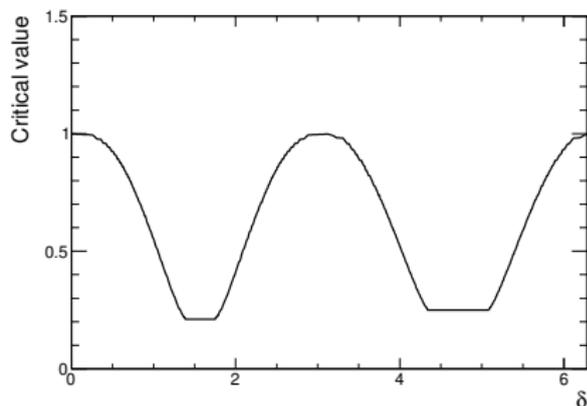

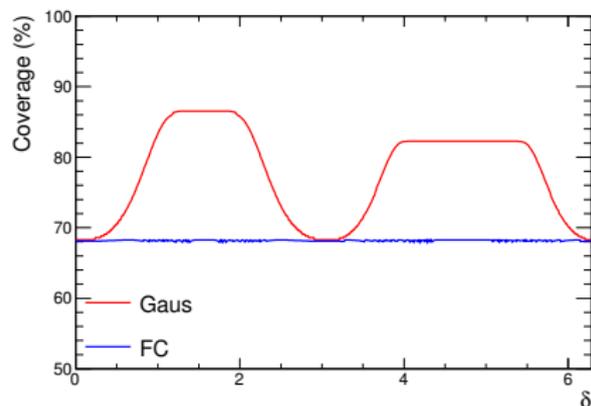

- ▶ Model  $\delta_{CP}$  behaviour, neglect hierarchy and octant
- ▶ Expected number of events =  $33 - 6 \sin \delta$
- ▶ Throw experiments as gaussian numbers  $N \pm \sqrt{N}$
- ▶ Eliminates complications from discontinuous event counts
- ▶ Can run full set of experiments in seconds

# Results

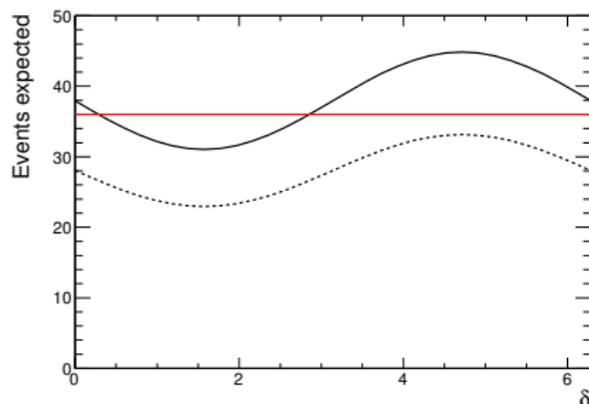

- ▶ Construct confidence intervals for many mock expts, evaluate coverage
- ▶ “Gaus” ( $\Delta\chi_{\text{crit}}^2 = 1$ ) works far from extremes
- ▶ *i.e.* when  $\chi_{\text{best}}^2$  will be zero
- ▶ Significantly overcovers elsewhere

# Results

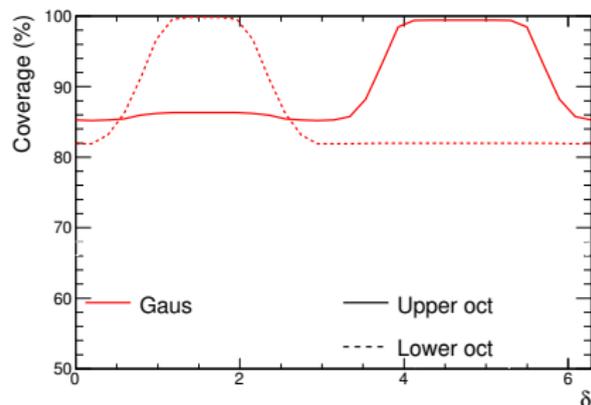

- ▶ Construct confidence intervals for many mock expts, evaluate coverage
- ▶ “Gaus” ( $\Delta\chi_{\text{crit}}^2 = 1$ ) works far from extremes
- ▶ *i.e.* when  $\chi_{\text{best}}^2$  will be zero
- ▶ Significantly overcovers elsewhere, big FC correction required
- ▶ Correct FC coverage, as expected

## Upgraded toy

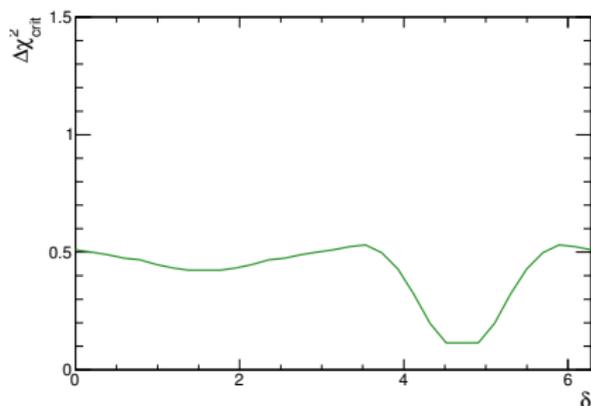

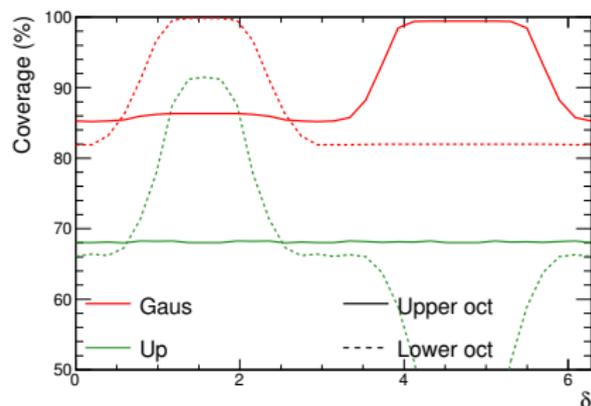

- ▶ Number expected =  $(0.8 \text{ or } 1.2)(33 - 6 \sin \delta)$
- ▶ Modelled after octant
- ▶ People are more willing to separate results by hierarchy, but want  $\theta_{23}$  to be “profiled out”
- ▶ Goal is to make correct intervals in  $\delta$  independent of true octant
- ▶ Red line shows one example experiment

## Critical value strategies

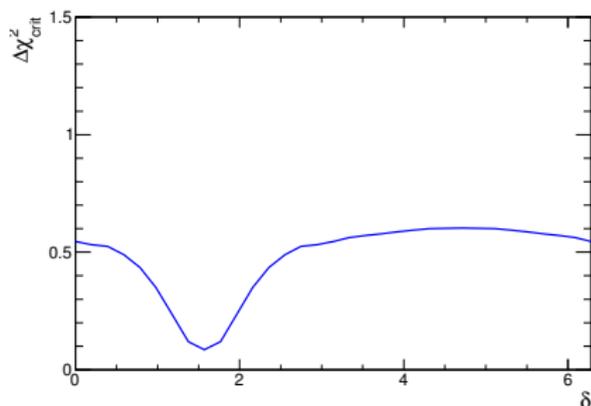

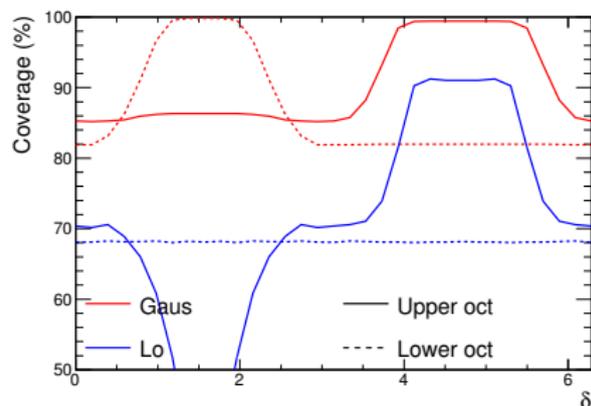

- ▶ “Gaus” ( $\Delta\chi_{\text{crit}}^2 = 1$ ) heavily overcovers in all cases

# Critical value strategies

- ▶ “Gaus” ( $\Delta\chi_{\text{crit}}^2 = 1$ ) heavily overcovers in all cases
- ▶ “Up” throws all FC experiments from the upper octant
- ▶ Obviously perfect for upper octant, still very bad for lower

# Critical value strategies

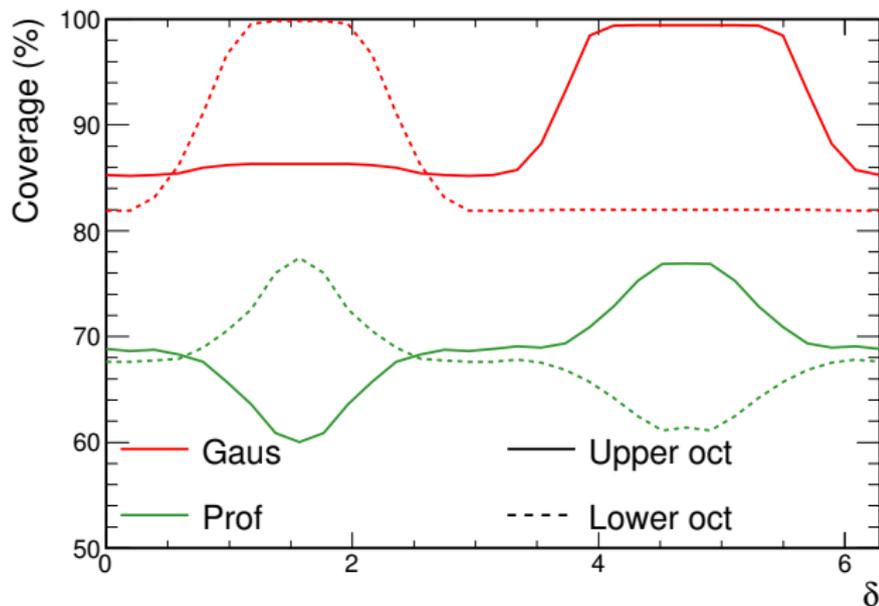

- ▶ “Lo” throws all experiments from the lower octant
- ▶ See how the necessary  $\Delta\chi_{\text{crit}}^2$  differs from “Up”

## “Profile” method

- ▶ How can we possibly satisfy the needs of both true octants?
- ▶ A possible loophole: allow  $\Delta\chi_{\text{crit}}^2$  to depend on the observed data
- ▶ For each  $\delta$  throw experiments in the octant the data favour
- ▶ Still will sometimes use  $\Delta\chi_{\text{crit}}^2$  for the wrong octant, but may be rare enough?
- ▶ Call this method “Prof”

## Critical value strategies

- ▶ Coverage properties are better, still not good enough to make people comfortable

## Crazy ideas

- ▶ One can of course always guarantee no undercoverage by using the largest  $\Delta\chi_{\text{crit}}^2$  for any true value of the suppressed variable
- ▶ Substantially understating the power of the experiment is not popular

## Crazy ideas

- ▶ One can of course always guarantee no undercoverage by using the largest  $\Delta\chi_{\text{crit}}^2$  for any true value of the suppressed variable
- ▶ Substantially understating the power of the experiment is not popular
  
- ▶ In this very specific case one could balance the competing needs of lower and upper octant by carefully picking the two ends of a range in  $N$  that you'll accept for each  $\delta$
- ▶ Not generic
- ▶ Gives up all of the benefits of using  $\Delta\chi^2$  as the ordering criterion

# Pragmatism

- ▶ No satisfactory way to “integrate out” hierarchy or octant possible
- ▶ Continue to plot four curves
  
- ▶ Problem really stems from large impact and bimodality of  $\theta_{23}$
- ▶ Studies beyond the scope of this toy show profiling over  $\theta_{23}$  but constrained within a particular octant works much better
- ▶ For other parameters approximation that  $\Delta\chi_{\text{crit}}^2$  does not depend on them is far better
  
- ▶  $\nu_{\mu}$  contours much better behaved
- ▶  $\theta_{23}$  bimodal, but so degenerate it doesn't matter

# Conclusion

- ▶ Variety of ways to incorporate ND / external constraints
- ▶ Mix of Bayesian and frequentist approaches to set limits
- ▶ Starting to want to accept/reject specific points as well as provide a range
- ▶ Convolutions of oscillation formulae can provide interesting torture tests
